# Our research project 2009-

#### Problem

- understand what is quantity of information in timed words/languages
- compute it for timed regular languages
- create timed theory of codes, with channels, transducers etc
- get insights, apply to other theoretical questions
- go to applications to data transmission/compression

# Our research project 2009-

Size of (Information in) Languages

## Defining entropy (Chomsky-Miller)

- Take a language L ⊂ Σ<sup>\*</sup>.
- Count the words of length n: find  $\#L_n$
- Typically it grows exponentially
- Growth rate entropy  $\mathcal{H}(L) = \limsup \frac{\log_2 \# L_n}{n}$

Size of (Information in) Languages

## Defining entropy (Chomsky-Miller)

- Take a language L ⊂ Σ<sup>\*</sup>.
- Count the words of length n: find  $\#L_n$
- Typically it grows exponentially
- Growth rate entropy  $\mathcal{H}(L) = \limsup \frac{\log_2 \# L_n}{n}$

#### Explaining the definition

- Size measure:  $\#L_n \approx 2^{n\mathcal{H}}$ .
- Compression rate (in bits/symbol) for a typical  $w \in L$ , i.e.  $|w.zip| \approx \mathcal{H}|w|$
- Information content of a typical  $w \in L$  (bits/symbol)
- Topological entropy of a subshift.

5/44

# Entropy of Regular Languages

## Computing $\mathcal{H}(L(A))$ for a deterministic A

- Remove unreachable states
- Write down the adjacency matrix *M*.
- Compute  $\rho = \rho(M)$  its spectral radius.
- Then  $\mathcal{H} = \log \rho$ .

(4) (日本)

# Entropy of Regular Languages

## Computing $\mathcal{H}(L(A))$ for a deterministic A

- Remove unreachable states
- Write down the adjacency matrix M.
- Compute  $\rho = \rho(M)$  its spectral radius.
- Then  $\mathcal{H} = \log \rho$ .

## Proof

- $\#L_n(i \to j) = M_{ii}^n$
- Hence  $#L_n =$ sum of some elements of  $M^n$
- Perron-Frobenius theory of nonnegative matrices  $\Rightarrow \#L_n \approx \rho(M)^n \Rightarrow \mathcal{H}(L) = \log \rho(M)$

## Entropy of regular languages — example

- Words of lengths 0, 1, 2...: {ɛ}; {a, b}; {aa, ab, ba}; {aaa, aab, aba, baa, bab, bac}; {aaaa, aaab, aaba, abaa, abab, abac, baaa, bab, baca, baba, babb} ...
- Cardinalities: 1,2,3,6,11, ...
- $|L_n| \approx (1.80194)^n = \rho(M)^n = 2^{0.84955n}$ . entropy:  $\mathcal{H} = \log \rho(M) \approx 0.84955$ .

# Constrained channel coding

#### Given:

- Language S: possible messages issued by a source
- Language C: words that can be transmitted through a channel

### Goal:

• How to encode the messages for transmission?

• • = • • = •

# The EFMPlus code [Immink]

Used in DVD.

Description of the coding problem

- Source: {0,1}\*
- Channel: words of  $\{0,1\}^*$  without blocks 11, 101, 0000000000.

#### Efficiency of EFMPlus

- EFMPlus rate: 1/2.
- Optimal rate for this problem: 0.5418.

・ ロ ト ・ 同 ト ・ 三 ト ・ 三 ト

## Discrete case: definition of coding

#### Definition

#### $\phi: S \rightarrow C$ is an encoding with rate $\alpha$ and delay d if:

- Its rate is bounded by  $\alpha$ :  $|w| \ge \alpha |\phi(w)|$  : no size explosion
- It is injective with delay d: if |w| = |w'| et  $|u| = |u'| \ge d$  then  $\phi(wu) = \phi(w'u') \Rightarrow w = w'$ : decoding is possible

## Discrete case: characterization

```
Definition (a key tool)
```

The entropy rate of a language:  $h(L) = \lim_{n \to \infty} \frac{\log |L_n|}{n}$ 

#### Intuition:

h(L) is the information content of the language in bits/symbol

## Theorem (Existence of encodings)

For "regular" S and C:

- Sufficient condition:  $\alpha h(S) < h(C)$
- Necessary condition:  $\alpha h(S) \leq h(C)$

- Onclusion

Timed automata and languages: our main object of study A distance on timed words, because we should proceed with some precision  $\varepsilon$  wrt to a distance  $\varepsilon$ -entropy and capacity: a standard way of measuring *information* in continuous sets

# Pseudo-distance on timed words - [ABD18]

## Required: a distance

- should be meaningful
- should compare timed words with different numbers of events
- should be compact on bounded duration timed words

#### Definition

Given 
$$u=(a_1,t_1)\dots(a_n,t_n)$$
 and  $v=(b_1,s_1)\dots(b_m,s_m)$ , let

$$\overrightarrow{d}(u,v) = \overleftarrow{d}(v,u) = \max_{i} \min_{j} \{ |t_i - s_j| : b_j = a_i \}; \quad d = \max(\overrightarrow{d}, \overleftarrow{d})$$

#### Comment

 $\vec{d}(u, v)$  is small if for each event in u, exists a matching event in v, at a close date.

Reminder: information in continuous sets

- Q: Given a continuous set M, how much information contains x ∈ M (what is the file size to describe x)?
- A:  $\infty$ , infinitely many bits needed... it was a stupid question.

Reminder: information in continuous sets

- Q: Given a continuous set M, how much information contains x ∈ M (what is the file size to describe x)?
- A:  $\infty$ , infinitely many bits needed...it was a stupid question.
- Q: Given a continuous set M, and ε > 0, how much information contains x ∈ M (what is the file size to describe x with precision ε > 0)?
- A: Nice question, the answer by Kolmogorov & Tikhomirov is ε-entropy (and ε-capacity).

# Defining $\varepsilon$ -entropy

## Definition ( $\varepsilon$ -net)

Given M a metric space and  $\varepsilon > 0$ , a subset  $S \subset M$  is an  $\varepsilon$ -net if  $\forall x \in M \exists y \in S : d(x, y) < \varepsilon$ If M is compact, a finite  $\varepsilon$ -net always exists.

#### Definition ( $\varepsilon$ -entropy)

$$H_{\varepsilon}(M) = \log \min\{|S| : S \subset M \text{ an } \varepsilon\text{-net}\}$$

### Explanation

To describe  $x \in M$  with precision  $\varepsilon$  in  $H_{\varepsilon}(M)$  bits:

- fix an optimal ε-net S;
- choose  $y \in S$  such that  $d(x, y) < \varepsilon$ ;
- write in binary the ordinal number of y in S.

< ロ > < 同 > < 回 > < 回 >

Entropy & capacity: interpretation & inequalities

#### $\varepsilon$ -entropy

Minimal information needed to describe A with precision  $\varepsilon$ 

#### $\varepsilon\text{-capacity}$

Maximal information distinguishable in A if observed with error  $\varepsilon$ 

#### Inequalities

# $\mathcal{C}_{2\varepsilon}(A) \leq \mathcal{H}_{\varepsilon}(A) \leq \mathcal{C}_{\varepsilon}(A)$

Eugene Asarin, Aldric Degorre , Cătălin Dim

## Our measure of information per time unit

Definition (Bandwidth of a timed language)

$$\mathcal{BH}_{\varepsilon}(L) = \limsup_{T \to \infty} \frac{\mathcal{H}_{\varepsilon}(L_T)}{T} \qquad \qquad \mathcal{BC}_{\varepsilon}(L) = \limsup_{T \to \infty} \frac{\mathcal{C}_{\varepsilon}(L_T)}{T}$$

Shorthands:  $\mathcal{B}$  for any of  $\mathcal{BC}, \mathcal{BH}$ . Also  $\mathcal{B}(\mathcal{A})$  for  $\mathcal{B}(\mathcal{L}(\mathcal{A}))$ 

# Why bandwidth is relevant?

### Why, indeed?

- mathematically natural measure of info/time
- always  $< \infty$ , often > 0.
- our previous work on channel coding- Bernardo's MPRI internship, [Formats'22]
  - $\mathcal{B}(\mathsf{Source}) < \mathcal{B}(\mathsf{Channel}) \Rightarrow \mathsf{bounded}\mathsf{-delay} \mathsf{ coding is possible}$
  - $\mathcal{B}(\mathsf{Source}) > \mathcal{B}(\mathsf{Channel}) \Rightarrow \mathsf{it} \mathsf{ is impossible}$

up to some dirty details.

and it will provide theoretical insights

A B M A B M

# Two problems

## Problem (Our big challenge, not yet completely done)

Given a timed automaton A and  $\varepsilon$ , compute the bandwidth  $\mathcal{B}_{\varepsilon}(A)$ , as precisely as possible.

## Problem (In next slides)

Given a timed automaton A, explore the rough asymptotic behavior of  $\mathcal{B}_{\varepsilon}(A)$  w.r.t.  $\varepsilon \to 0$ .

# Outline

## 1 Introduction

- 2 Motivation 1: size/entropy of regular languages
- Operation Practical motivation: channel coding
- 4 Background and tools
- 5 Problem statement and motivation
- 6 The classification results
- Easy case: Computing the Bandwidth of Simply-Timed Graphs
- 8 Main result: Computing the Bandwidth of Meager Timed Automata
- Onclusion

# Classification

## Definition (Three classes)

# A timed language *L* is meager whenever $\mathcal{B}_{\varepsilon}(L) = O(1)$ normal whenever $\mathcal{B}_{\varepsilon}(L) = \Theta(\log 1/\varepsilon)$ obese whenever $\mathcal{B}_{\varepsilon}(L) = \Theta(1/\varepsilon)$ as $\varepsilon \to 0$ .

Information in timed words

## Before we start the examples

#### Trivial remarks on information

One letter  $a \in \Sigma$  contains  $\log(\#\Sigma)$  bits, i.e.  $\mathcal{H}_{\varepsilon}(\Sigma) = \mathcal{C}_{\varepsilon}(\Sigma) = \log(\#\Sigma)$ . One real number  $x \in [5, 6]$  (with precision  $\varepsilon$ ) contains  $\log(1/\varepsilon)$  bits, i.e.  $\mathcal{H}_{\varepsilon/2}[5, 6] \approx \mathcal{C}_{\varepsilon}[5, 6] \approx \log(1/\varepsilon)$ .

- 4 回 ト 4 三 ト 4 三 ト

Meager automata:  $\mathcal{BH}_{\varepsilon} = O(1)$ , simple examples

#### Explanation of their meagerness

Impossible to encode info in reals, on the long run. Only discrete information.

Eugene Asarin, Aldric Degorre , Cătălin Dim

Information in timed words

2024, MPRI 2-8-2 27 / 44

・ ロ ト ・ 同 ト ・ 三 ト ・ 三 ト

Normal automata:  $\mathcal{BH}_{\varepsilon} = \Theta(\log 1/\varepsilon)$ 

#### Explanation of its normality

Every 5-6 sec we can freely choose 2 real durations. Each time we transmit log  $1/\varepsilon$  bits. Thus  $\mathcal{B}_{\varepsilon} = \frac{2}{5} \log 1/\varepsilon$  bit/sec

Eugene Asarin, Aldric Degorre , Cătălin Dim

- 4 回 ト 4 ヨ ト 4 ヨ ト

Obese automata: $\mathcal{BH}_{arepsilon}=\Theta(1/arepsilon)$ 

#### Explanation of their obesity

- Every  $\varepsilon$  sec we transmit one bit (a or nothing).  $\mathcal{B} = 1/\varepsilon$  bit/sec.
- Every  $\varepsilon$  sec we transmit 3 bits (subset of  $\{a, b, c\}$ ), thus  $\mathcal{B} = 3/\varepsilon$ .

・ ロ ト ・ 同 ト ・ 三 ト ・ 三 ト

Obese automata: $\mathcal{BH}_{arepsilon}=\Theta(1/arepsilon)$ 

#### Explanation of their obesity

- Every  $\varepsilon$  sec we transmit one bit (a or nothing).  $\mathcal{B} = 1/\varepsilon$  bit/sec.
- Every  $\varepsilon$  sec we transmit 3 bits (subset of  $\{a, b, c\}$ ), thus  $\mathcal{B} = 3/\varepsilon$ .
- After 1 sec of transmission we spend 5 sec to reset clocks,  $\mathcal{B} \approx 1/6\varepsilon$ .

## Towards structural characterization of the 3 classes

Plan: given a bounded deterministic timed automaton

- Split its states into regions (unit "triangles" simplices)
- Trim it (remove useless states)
- Map each edge (and path) into a finite monoid
- Define two patterns<sup>a</sup> NM and O (in terms of monoids)
- Characterize classes by presence/absence of patterns

<sup>a</sup>non-meagerness and obesity terns

# Our results on one slide

We define two patterns NM and O

### Theorem (Structural criteria)

- $\mathcal{A}$  contains pattern  $\mathsf{NM} \Rightarrow \mathcal{B}_{\varepsilon}(\mathcal{A}) = \Omega(\log 1/\varepsilon)$  (non-meager).
- $\mathcal{A}$  does not contain  $NM \Rightarrow \mathcal{B}_{\varepsilon}(\mathcal{A}) = O(1)$  (meager).
- A contains pattern  $O \Rightarrow \mathcal{B}_{\varepsilon}(\mathcal{A}) = \Omega(1/\varepsilon)$  (obese).
- $\mathcal{A}$  does not contain  $O \Rightarrow \mathcal{B}_{\varepsilon}(\mathcal{A}) = O(\log 1/\varepsilon)$  (non-obese).

#### Theorem (Classification)

Every deterministic timed automaton is meager or normal or obese. The classification problem is PSPACE-complete.

# Bandwidth of Simply-Timed Graphs

#### Definition

For a set of timed words S, its size  $\Upsilon(S)$  is the cardinality of the largest 0-separated set in S

#### Definition

The growth rate of an STG  ${\mathcal A}$  is defined as

$$eta(\mathcal{A}) = \lim_{T o \infty} rac{\log \Upsilon(L_T(\mathcal{A}))}{T},$$

#### Remark

Let 1/D be the smallest non-zero timing in the STA. For  $\varepsilon < 1/2D$  the growth rate coincides with both bandwidths:

$$\mathcal{BC}_{\varepsilon}(\mathcal{A}) = \mathcal{BH}_{\varepsilon}(\mathcal{A}) = \beta(\mathcal{A}).$$

Eugene Asarin, Aldric Degorre , Cătălin Dim

ヘロト 人間ト 人間ト 人間ト

# Computing the growth rate of an STG

#### 0-elimination and determinization

#### z-matrix and characteristic equation

$$m_{ij}(z) = \sum_{(q_i,d,a,q_j)\in\Delta} z^d,$$

$$M(z) = \begin{pmatrix} z^3 + 2z^5 & z^3 \\ z^2 & z^2 \end{pmatrix}$$

• Characteristic equation: det(I - M(z)) = 0

- *z*<sub>0</sub>: its root of smallest modulus
- The growth rate:  $eta(\mathcal{A}) = -\log_2 |z_0|$

• In our case: 
$$2z^7 - 2z^5 - z^3 - z^2 + 1 = 0$$
,  
 $z_0 \approx 0.698776, \beta(\mathcal{A}) \approx 0.517098$

# Barycenters of a clock region

## Definition (faces of a region)

A (k - 1)-dimensional face is the convex hull of any subset of k > 0 vertices.

Faces are simplices. Each vertex or the whole closed region are considered as faces.

## Definition (barycenters of a region)

To each such face f with vertices  $v_1, \ldots, v_k$  we associate its *barycenter*  $\alpha(f) = \frac{1}{k} \sum_{i=1}^{k} v_k$ 

# From Meager Automata to STG, 1/2

# Definition (barycentric abstraction of a transition $p \xrightarrow{\delta} q$ )

Link barycenters  $b_1$  of p and  $b_2$  of q whenever their faces have the same dimension and  $L_{\delta}(b_1, b_2) = \{ta\}$  is a singleton. Label with duration t and letter a.

# From Meager Automata to STG, 2/2

Definition (barycentric abstraction of an RsTA)

Abstract every transition of A, the resulting STG is denoted  $\alpha(A)$ .

# Main results

Theorem (characterisation of the bandwidth of Meager TA)

• barycentric abstraction preserves the bandwidth of Meager RsTA

 $\mathcal{B}_{arepsilon}(\mathcal{A})=\mathcal{B}_{0}(lpha(\mathcal{A}))$  for arepsilon small enough

• thus the bandwidth of meager TA is computable (as log of an algebraic number)

## Overall algorithm: given a meager TA

- put it into region-split form
- compute its barycentric abstraction (STG)
- proceed with 0-elimination and determinization
- write down the characteristic equation
- find its smallest root
- compute the bandwidth

# Example: computing the bandwidth of a meager TA A meager RsTA, barycentric abstraction, 0-elimination

#### z-matrix and bandwidth

$$M(z) =$$
